

Signals in a Small Synthetic Sensor Array

Abstract

This synthetic paper describes a deterministic sensor-array experiment designed solely to exercise a local review pipeline.

1. Method

The estimator is the arithmetic mean of the four observations. No learned parameters or external data are used.

The observations are 0.90, 1.00, 1.05, and 1.10 in the same arbitrary unit.

Signals in a Small Synthetic Sensor Array

2. Results and limitations

The deterministic estimator returns 1.0125 for the fixture values.

It does not establish robustness, statistical significance, external validity, or suitability for a physical sensor.

This document is intentionally small and deterministic so import, extraction, review validation, backup, and deletion tests remain reproducible.
